

Millerite and Bornite Identified in Lady Alma Core

Highlights

- Samples from Lady Alma holes CHRCD004 and CHD005B-W1 were sent for scanning electron microscopy (SEM)
- SEM confirmed sulphide assemblage of pentlandite-pyrrhotite-chalcopyrite initially identified in petrography
- Nickel from pentlandite indicates a tenor of **30-40% Ni** with one sample indicating up to **66% Ni** from millerite
- Cobalt identified in pentlandite ranges from **4-6% Co**
- Copper tenor is primarily from chalcopyrite, grading between **33-40% Cu**
 - Bornite, where present in chalcopyrite tenors up to **62% Cu**
- Presence of high tenor primary magmatic sulphides in both petrography and scanning electron microscopy confirms the potential of hosting a substantial magmatic nickel-copper-cobalt sulphide system

Peak Minerals Limited (ASX: **PUA**) (**Peak** or the **Company**) is pleased to provide an update on the petrographic analysis of mineralisation from the Lady Alma Prospect within the Green Rocks Project, Western Australia.

Samples from **CHRCD004** and **CHD005B-W1** (refer Figure 4 for locations) showed the presence of an intercumulus sulphide consisting of pyrrhotite, chalcopyrite and pentlandite. The samples were sent for scanning electron microscopy (**SEM**) which confirmed the three-phase sulphide identified in petrography as well as minor millerite and bornite. The intersected mineralisation provides insights into the potential grade of the system. Calculating Ni tenor is further support of a magmatic nickel-copper system. Moving Loop Electromagnetics (**MLEM**) is planned in May to help target the magmatic source of this mineralisation prior to drill testing.

Peak CEO, Jennifer Neild commented:

*“The results from the **SEM** combined with the petrography and the geochemistry all support the presence of a magmatic nickel-copper system. The presence of millerite and bornite is extremely encouraging, this is the style of mineralisation the Company was hoping for. The drilling late in Q2 is targeting wider zones of this type of mineralisation.”*

Two samples were submitted to ALS Metallurgy for **SEM** analysis. A total of 5 measurements were taken from each of the two samples in a way to maximise the surface area of the sulphide present. The samples selected were the massive pyrrhotite from **CHRCD004** and the stringer of chalcopyrite from **CHD005B-W1**. The details of this drilling and additional assays are available in ASX release dated 18 March 2022¹.

Figure 1: The SEM Image on the left shows the massive pyrrhotite with coarse grained pentlandite and chalcopyrite. The image on the right is the drill core analysed.

From **CHRCD004**, the massive pyrrhotite from 374.4m was analysed to assess the tenor of the nickel. The initial petrography showed the presence of pentlandite as coarse grains within the pyrrhotite. The original assay sample returned **0.46% Ni** and **0.17% Cu** over 0.3m. The SEM analysis identified the pentlandite grades **32.34% Ni** and **5.8% Co**, the chalcopyrite grades **34.46% Cu** and the pyrrhotite is barren (refer Table 1).

¹ ASX Announcement 18 March 2022 - 'Nickel Sulphide Mineralisation Confirmed at Green Rocks'.

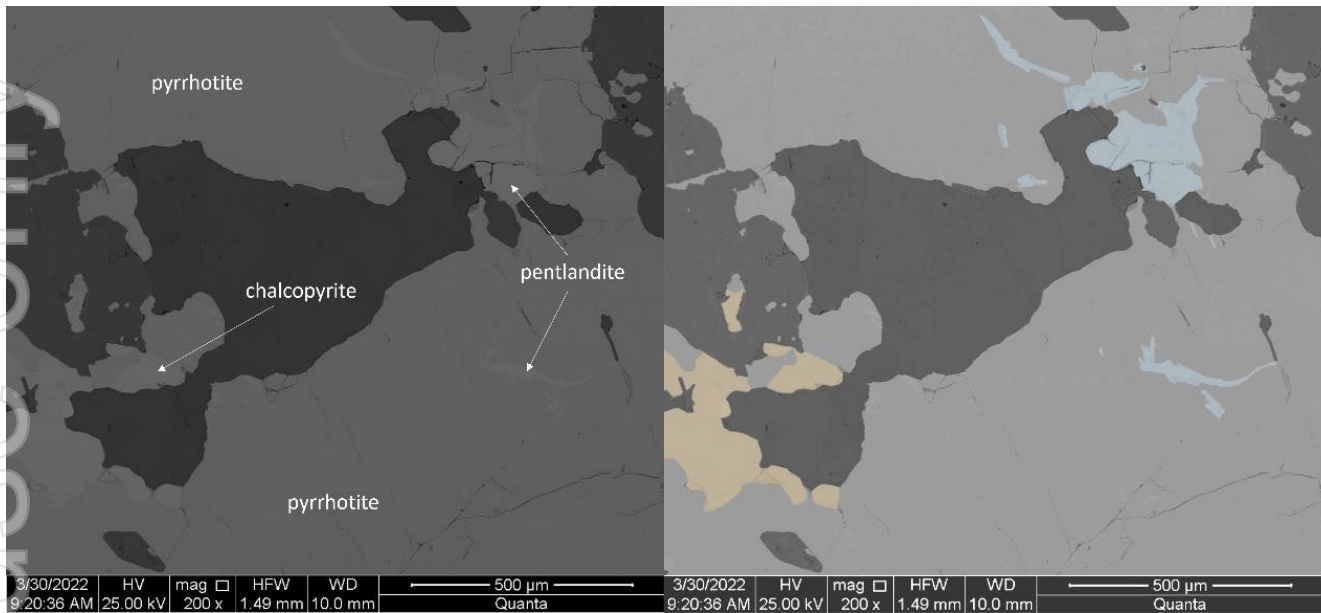

Figure 2: Interpretation/outline of the minerals identified in the SEM image (left side). The right image highlights the chalcopyrite in yellow and pentlandite in blue.

Figure 2 shows the outlines of the pentlandite within the massive pyrrhotite.

From CHD005B-W1, the copper stringer at 827.87m graded **4.95% Cu** and **0.70% Ni** over 0.13m. Figure 3 shows the presence of bornite, as exsolution lamellae within chalcopyrite. The SEM analysis identified the chalcopyrite which grades **33.97% Cu** and the bornite grading **62.4% Cu**.

Figure 3: The SEM image on the left shows magnetite crystals on the left side with chalcopyrite on the right. The bornite occurs as exsolution lamellae within the chalcopyrite. The presence of bornite, increases the tenor of copper. The image on the right is the drill core.

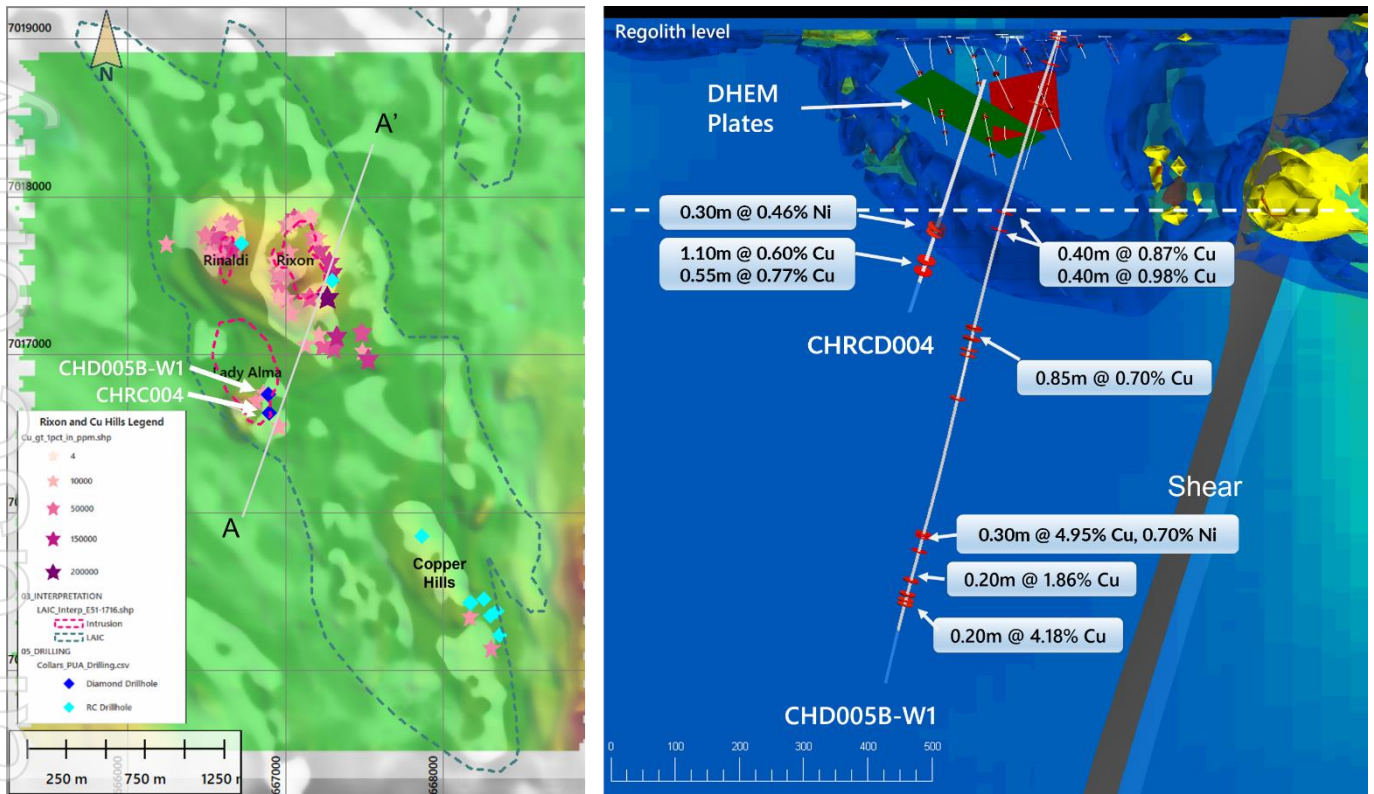

Figure 4: Location map of the diamond holes drilled at Lady Alma by Peak in 2021 (left), part of the section A-A' showing drillhole paths and selected intervals (right).

Competent Person's Statement

The information in this announcement that relates to new exploration results is based on information compiled by Ms Barbara Duggan, who is a Member of the Australian Institute of Geoscientists. Ms Duggan is employed by Peak Minerals Limited. Ms Duggan has sufficient experience which is relevant to the style of mineralisation and type of deposit under consideration and to the activity which she is undertaking to qualify as a Competent Person as defined in the 2012 Edition of the 'Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves'. Ms Duggan consents to the inclusion in this announcement of the matters based on her information in the form and context in which it appears.

The information in this announcement that relates to historical exploration results were reported by the Company in accordance with listing rule 5.7 on 18 March 2022 (*Nickel Sulphide Mineralisation Confirmed at Green Rocks*). The Company confirms that the form and context in which the Competent Person's findings are presented have not been materially modified from the original market announcement.

APPENDIX A: Table Summaries (all coordinates in MGA 94, Z50)

Table 1: Drill collar locations.

APPENDIX B: JORC Code, 2012 Edition – Table 1
**Section 1: Sampling Techniques and Data
(Criteria in this section apply to all succeeding sections.)**

Criteria	JORC Code explanation	Comments
Sampling techniques	<ul style="list-style-type: none"> Nature and quality of sampling (eg cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling. 	<p>HQ3/NQ2 diamond drill core was submitted for analysis. All samples were half core that was cut with an almonti saw. The only exception is for the regular duplicates down hole that were cut into quarters so that half of the core remained in the tray.</p> <p>SEM Analysis: 2 pieces of drill core were submitted for a non-destructive analysis whereby the sample is irradiated with electrons resulting in the emission of x-rays characteristic to the elements present.</p>
	<ul style="list-style-type: none"> Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used. 	<p>Core was cut into two equal halves, approximately 1 cm to the left of the orientation line where possible. The left side was always sent to the laboratory to leave the orientation lines in the tray.</p>
	<ul style="list-style-type: none"> Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (eg 'reverse circulation drilling was used to obtain 1 m samples from which 3 kg was pulverised to produce a 30 g charge for fire assay'). In other cases, more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (eg submarine nodules) may warrant disclosure of detailed information. 	<p>Sample intervals are based on geological observations (lithological contacts, mineralisation, alteration, etc). Minimum core sampled was 0.3m except for 6 mineralised samples which were between 0.13m and 0.25m in length. A total of 791 samples were sent to the laboratory 45 CRM's and 35 duplicate samples.</p> <p>SEM Analysis: Each piece of drill core was analysed in 5 different spots with multiple measurements taken each time.</p>
Drilling techniques	<ul style="list-style-type: none"> Drill type (eg core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (eg core diameter, triple or standard tube, depth of diamond tails, face-sampling bit or other type, whether core is oriented and if so, by what method, etc). 	<p>Standard tube NQ2 and HQ3 diamond drilling was undertaken.</p> <p>All NQ2 core was oriented using the Trucore orientation system.</p>
Drill sample recovery	<ul style="list-style-type: none"> Method of recording and assessing core and chip sample recoveries and results assessed. 	<p>Core recoveries were collected for every drill run completed. The core recovered is physically measured by tape measure and the length is recorded for every 'run'. Core recovery is calculated as a percentage recovery, which is logged and recorded into the database.</p>
	<ul style="list-style-type: none"> Measures taken to maximise sample recovery and ensure representative nature of the samples 	<p>Diamond drilling by nature collects relatively uncontaminated core samples. These are cleaned at the drill site to remove drilling fluids and cuttings to present clean core for logging and sampling.</p>
	<ul style="list-style-type: none"> Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material. 	<p>No sample bias is present as core recoveries are good.</p>
Logging	<ul style="list-style-type: none"> Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical studies. 	<p>All drill holes were logged for lithology, alteration, mineralisation, structure, and weathering by a geologist. Data is then captured in a database in a database appropriate for mineral resource estimation.</p>

	<ul style="list-style-type: none"> Whether logging is qualitative or quantitative in nature. Core (or costean, channel, etc) photography. 	All drill core are photographed in the core tray, with individual photographs taken of each tray both dry and wet. Logging conducted is both qualitative and quantitative.
	<ul style="list-style-type: none"> The total length and percentage of the relevant intersections logged. 	All drill holes were logged in their entirety.
Sub-sampling techniques and sample preparation	<ul style="list-style-type: none"> If core, whether cut or sawn and whether quarter, half or all core taken. 	Diamond drill core was cut in half. Half the core was submitted for analysis and the remaining half was stored securely for future reference and potentially further analysis if ever required.
	<ul style="list-style-type: none"> If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry. 	Only diamond core drilling was completed.
	<ul style="list-style-type: none"> For all sample types, the nature, quality and appropriateness of the sample preparation technique. 	Sample preparation was completed by ALS Laboratories in Perth. Up to 3kg of sample are pulverised to <75 µm. SEM analysis: A small piece of the mineralised samples were cut and placed in a 'puck' held by resin for analysis.
	<ul style="list-style-type: none"> Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples. 	QAQC reference samples and duplicates were routinely submitted with each sample batch. Additionally, the QAQC from the laboratory was also collected.
	<ul style="list-style-type: none"> Measures taken to ensure that the sampling is representative of the <i>in-situ</i> material collected, including for instance results for field duplicate/second-half sampling. 	Duplicate samples were routinely submitted every 25 samples.
	<ul style="list-style-type: none"> Whether sample sizes are appropriate to the grain size of the material being sampled. 	Samples ranged from 0.3m to a maximum of 1.2m to follow lithological, mineralisation and or alteration contacts. The only exception is 6 mineralised zones that were between 0.13 to 0.25m.
	<ul style="list-style-type: none"> The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total. 	All samples were sent to ALS laboratory for multi-element analysis (4 Acid digestion with ICP-MS and ICP-AES finish) and Au, Pd, and Pt analysis (30g lead fire assay with ICP-AES finish). This method is appropriate for characterisation of lithogeochemistry and determination of mineralisation. All samples that exceeded the upper limit of detection were analysed for Ore Grade Cu or Nickel by 4 acid digestion with an ICP finish. Of the samples analysed, 6 were chosen for full PGE analysis (Pt, Pd, Au, Rh, Ir, Os, Ru) by 30g nominal sample weight for nickel sulphide collection fire assay and ICP-MS finish. SEM analysis: The analysis method works by scanning the sample with electron beams. The electrons in the beam interact with the sample and produce various signals that can be measured. The elements measured can give a true indication of the amount of copper and nickel, for example, present in the sample.
Quality of assay data and laboratory tests	<ul style="list-style-type: none"> For geophysical tools, spectrometers, handheld XRF instruments, etc, the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc. 	All analytical results listed are from an accredited laboratory.
	<ul style="list-style-type: none"> Nature of quality control procedures adopted (eg standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (ie lack of bias) and precision have been established. 	For all sampling, CRM's were utilised every 20 samples with every 5 th CRM being a blank. Duplicates were collected every 25 samples. In addition, QAQC data from the lab is also collected and stored in the database.
	<ul style="list-style-type: none"> The verification of significant intersections by either independent or alternative company personnel. 	Results were reviewed by the chief geologist with the laboratory repeating selected intervals. Significant results are: >1% Cu, >0.4% Ni, and >0.3% S.
Verification of sampling and assaying	<ul style="list-style-type: none"> The verification of significant intersections by either independent or alternative company personnel. 	Results were reviewed by the chief geologist with the laboratory repeating selected intervals. Significant results are: >1% Cu, >0.4% Ni, and >0.3% S.

For personal use only

	<ul style="list-style-type: none"> •The use of twinned holes 	No twinned drill holes were completed.
	<ul style="list-style-type: none"> •Documentation of primary data, data entry procedures, data verification, data storage (physical and electronic) protocols. 	Data was capture into digital spreadsheets. Data was checked and verified. Digital files were imported into the PUA electronic database. All physical sampling sheets are filed and scanned electronically.
	<ul style="list-style-type: none"> •Discuss any adjustment to assay data. 	No adjustments were made to the assay data.
Location of data points	<ul style="list-style-type: none"> •Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation. 	Drill collars were collected by differential GPS except for CHD005A which could not be cased and collapsed.
	<ul style="list-style-type: none"> •Specification of the grid system used. 	All collar locations are reported in GDA1994 MGA, Zone 52 coordinate system.
	<ul style="list-style-type: none"> •Quality and adequacy of topographic control. 	Topography based on publicly available data.
Data spacing and distribution	<ul style="list-style-type: none"> •Data spacing for reporting of Exploration Results. 	Diamond drill holes were drilled to selectively target historic geophysical targets that remained untested.
	<ul style="list-style-type: none"> •Whether the data spacing and distribution is sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied. 	The drill spacing is insufficient to estimate a mineral resource.
	<ul style="list-style-type: none"> •Whether sample compositing has been applied. 	Sample compositing has been applied. Results reported are length weighted averages.
Orientation of data in relation to geological structure	<ul style="list-style-type: none"> •Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known, considering the deposit type. 	Based on the logging of the drilling and interpretation of geology the orientation of the drilling was down the edge of the contact. The Company is still working to understand the finer details of the target but no apparent sampling bias is present.
	<ul style="list-style-type: none"> •If the relationship between the drilling orientation and the orientation of key mineralised structures is considered to have introduced a sampling bias, this should be assessed and reported if material. 	The drilling intercepts reported are downhole. Further drilling is required to confirm the geometry of mineralisation.
Sample security	<ul style="list-style-type: none"> •The measures taken to ensure sample security. 	Diamond drill core was transported from site to the company's storage facility for logging and sampling. Samples were subsequently sent for a contractor or the laboratory for cutting and analytical analysis.
Audits or reviews	<ul style="list-style-type: none"> •The results of any audits or reviews of sampling techniques and data. 	No audits are documented to have occurred in relation to sampling techniques or data.

For personal use only

Section 2: Reporting of Exploration Results
(Criteria listed in the preceding section also apply to this section)

Criteria	JORC Code explanation	Commentary
Mineral tenement and land tenure status	<ul style="list-style-type: none"> Type, reference name/number, location and ownership including agreements or material issues with third parties such as joint ventures, partnerships, overriding royalties, native title interests, historical sites, wilderness or national park and environmental settings. 	<p>Peak Minerals Ltd has acquired 100% of Greenrock Metals Pty Ltd and thus 100% of E51/1716. E51/1716 is a granted tenement and is in full force. There are no known impediments towards the exploration and subsequent development of the Project. Greenrock Metals Pty Ltd retains a 1% NSR for all minerals sold.</p> <p>The tenement E51/1716 is part of the Company's Green Rocks Project which also includes CU2 WA Pty Ltd. Peak Minerals Ltd has acquired 100% of the shares of CU2 WA Pty Ltd. CU 2 WA Pty Ltd owns 100% interest in E51/1889 and E51/1934 which are granted tenure and are in full force. Peak Minerals has also acquired 100% of E51/1990, E51/2011 and Prospecting licenses P51/3199, P51/3200, P51/3201, P51/3202, P51/3203, P51/3204, P51/3205, P51/32019, P51/3220, P51/3221, P51/3222, P51/3223, P51/3224, P51/3225, P51/3226, P51/3227, P51/3228, P51/3229, P51/3230, P51/3231, P51/3232, P51/3233, P51/3234, P51/3235, P51/3236, P51/3237 and P51/3238.</p> <p>CU2 WA Pty Ltd also holds the right to earn in to the base and precious metals of E51/1818 by spending:</p> <ul style="list-style-type: none"> \$1,000,000 within 2 years for 51% (Minimum \$250,000 within 12 months of 26/11/2021) Not Less than \$2,000,000 within 2 years for an additional 19% (Stage 2 earn in) Completion of a PFS for an additional 10% (within 12 months of completing stage 2 earn in) CU2 WA Pty Ltd also holds the right to earn in to the base and precious metals of E51/1832 by spending: <ul style="list-style-type: none"> \$50,000 for 40% (Min \$25k within 6 months of 18/11/2020) for 40% Additional \$50,000 within 24 months for 40% <p>Minor sections of E51/1818, E51/1934 and E51/1990 are covered by an exclusion around Mt Yagahong.</p>
	<ul style="list-style-type: none"> The security of the tenure held at the time of reporting along with any known impediments to obtaining a licence to operate in the area. 	<p>No known impediments exist with respect to the exploration or development of the tenement.</p>
Exploration done by other parties	<ul style="list-style-type: none"> Acknowledgment and appraisal of exploration by other parties. 	<p>The Green Rocks Project has been explored by numerous companies since mid-1960s with the most recent being the Silver Swan Group (2008 – 2012) and Mithril Resources Ltd (2014-2015) and JV partner Taruga Minerals. Exploration by Matador Mining on E51/1716 was limited to desktop assessment and rock chip and soil sampling. Previous drilling, geochemical and geophysical surveys at the Copper Hills tenement (E51/1716) has demonstrated widespread copper mineralisation. Recent surface geochemistry by Taruga Minerals has identified base metal anomalism.</p> <p>Over the project area, reprocessing of the available geophysical coverages was completed. Further desktop review of historic data has supported the potential for magmatic copper mineralisation with data evaluation and summary still underway. Planning of additional geophysical surveys, mapping, surface sampling and drill targeting is currently underway.</p>

<p>Geology</p>	<ul style="list-style-type: none"> • Deposit type, geological setting and style of mineralisation. 	<p>Two types of mineralisation are present at the Green Rocks Project: magmatic sulphide mineralisation associated with mafic-ultramafic intrusions; and hydrothermal copper-gold mineralisation, which is controlled by a north-northwest trending shear zone, dipping moderately to steeply to the east. To the north the shear rotates towards more of a northwest orientation and can be traced for over 23km.</p> <p>The lithologies at Green Rocks consist of multiple gabbro to peridotite units which have intruded into greenstone ultramafic lithologies. The near surface mineralisation is interpreted to be hydrothermal/structural in nature and consists predominantly of malachite, chalcopyrite with lesser pyrite ± pyrrhotite associated with quartz veining and as anastomosing thin veinlets. The presence of magmatic sulphides in historic diamond drill core at 100m+ depth indicate a magmatic source for this mineralisation.</p> <p>In the east of the Green Rocks Project tenure, sedimentary horizons consisting of cherts, ironstone and BIFs are present as well as granitic intrusions</p>
<p>Drill hole Information</p>	<ul style="list-style-type: none"> • A summary of all information material to the understanding of the exploration results including a tabulation of the following information for all Material drill holes: <ul style="list-style-type: none"> - easting and northing of the drill hole collar - elevation or RL (<i>Reduced Level – elevation above sea level in metres</i>) of the drill hole collar - dip and azimuth of the hole - down hole length and interception depth - hole length. • If the exclusion of this information is justified on the basis that the information is not Material and this exclusion does not detract from the understanding of the report, the Competent Person should clearly explain why this is the case. 	<p>Drill hole locations are described in the body of the text and in Appendix A.</p> <p>No information material to the understanding of the exploration results has been excluded.</p>
<p>Data aggregation methods</p>	<ul style="list-style-type: none"> • In reporting Exploration Results, weighting averaging techniques, maximum and/or minimum grade truncations (eg cutting of high grades) and cut-off grades are usually Material and should be stated. • Where aggregate intercepts incorporate short lengths of high-grade results and longer lengths of low grade results, the procedure used for such aggregation should be stated and some typical examples of such aggregations should be shown in detail. 	<p>Length weighted averages are reported in the highlights and body of the announcement. A full listing of the individual intervals is reported in the body of the release above.</p> <p>Length weighted averages have been applied where necessary to calculate composite intervals. Calculations were completed by multiplying grade by interval length, adding all intervals together and dividing by the total sum of the interval.</p>

For personal use only

	<ul style="list-style-type: none"> The assumptions used for any reporting of metal equivalent values should be clearly stated. 	No metal equivalence data are reported.
Relationship between mineralisation widths and intercept lengths	<ul style="list-style-type: none"> These relationships are particularly important in the reporting of Exploration Results. 	Intervals of mineralisation reported are apparent widths. Further drilling is required to understand the geometry of mineralisation and therefore the true width of mineralisation.
	<ul style="list-style-type: none"> If the geometry of the mineralisation with respect to the drill hole angle is known, its nature should be reported. If it is not known and only the down hole lengths are reported, there should be a clear statement to this effect (eg 'down hole length, true width not known'). 	The geometry of the mineralisation below surface is not known at this time.
Diagrams	<ul style="list-style-type: none"> Appropriate maps and sections (with scales) and tabulations of intercepts should be included for any significant discovery being reported. These should include, but not be limited to a plan view of drill hole collar locations and appropriate sectional views. 	A Map of the drill holes have been included in the body of the announcement.
Balanced reporting	<ul style="list-style-type: none"> Where comprehensive reporting of all Exploration Results is not practicable, representative reporting of both low and high grades and/or widths should be practiced to avoid misleading reporting of Exploration Results. 	All information has been reported. Significant assays are considered copper greater than 0.2% and nickel assays greater than 0.4%.
Other substantive exploration data	<ul style="list-style-type: none"> Other exploration data, if meaningful and material, should be reported including (but not limited to): geological observations; geophysical survey results; geochemical survey results; bulk samples – size and method of treatment; metallurgical test results; bulk density, groundwater, geotechnical and rock characteristics; potential deleterious or contaminating substances. 	All other relevant data has been included within this report.
Further work	<ul style="list-style-type: none"> The nature and scale of planned further work (eg tests for lateral extensions or depth extensions or large-scale step-out drilling). 	Based on these results, further geophysical work is planned to better target prior to drill testing the area. It has been determined that the diamond drill holes did not hit the most prospective area within the intrusion.
	<ul style="list-style-type: none"> Diagrams clearly highlighting the areas of possible extensions, including the main geological interpretations and future drilling areas, provided this information is not commercially sensitive. 	A map noting the collar locations has been included.
